Validity of Pearson correlation calculations are based on several assumptions: o data is at continuous (scale/interval/ratio) level o data values are independent of each other; ie, only one pair of readings per participant is used o a linear relationship is assumed when calculating Pearson's coefficient of correlation

A Pearson correlation is a number between -1 and 1 that indicates the extent to which two variables are linearly related. The Pearson correlation is also known as the "product moment correlation coefficient" (PMCC) or simply "correlation". Pearson correlations are suitable only for metric variables (which include dichotomous variables).

The Pearson system was originally devised in an effort to model visibly skewed observations. It was well known at the time how to adjust a theoretical model to fit the first two cumulants or moments of observed data: Any probability distribution can be extended straightforwardly to form a location-scale family.
